Lectures 5-7

Simple Linear Regression

DSC 40A, Fall 2025

Agenda

- Simple linear regression.
- Correlation.
- Interpreting the formulas.
- Connections to related models.

Least squares solutions

• Our goal was to find the parameters w_0^* and w_1^* that minimized:

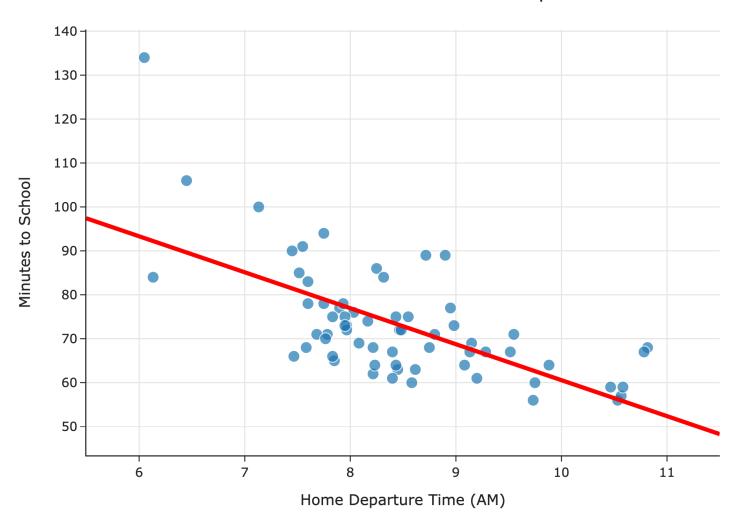

$$R_{ ext{sq}}(w_0,w_1) = rac{1}{n} \sum_{i=1}^n \left(y_i - (w_0 + w_1 x_i)
ight)^2$$

• To do so, we used calculus, and we found that the minimizing values are:

$$w_1^* = rac{\displaystyle\sum_{i=1}^n (x_i - ar{x})(y_i - ar{y})}{\displaystyle\sum_{i=1}^n (x_i - ar{x})^2} \qquad \qquad w_0^* = ar{y} - w_1^* ar{x}$$

• We say w_0^* and w_1^* are **optimal parameters**, and the resulting line is called the regression line.

Predicted Commute Time = 142.25 - 8.19 * Departure Hour

Now what?

We've found the optimal slope and intercept for linear hypothesis functions using squared loss (i.e. for the regression line). Now, we'll:

- See how the formulas we just derived connect to the formulas for the slope and intercept of the regression line we saw in DSC 10.
 - They're the same, but we need to do a bit of work to prove that.
- Learn how to interpret the slope of the regression line.
- Understand connections to other related models.
- Learn how to build regression models with multiple inputs.
 - To do this, we'll need linear algebra!

Question 🤔

Answer at q.dsc40a.com

Consider a dataset with just two points, (2,5) and (4,15). Suppose we want to fit a linear hypothesis function to this dataset using squared loss. What are the values of w_0^* and w_1^* that minimize empirical risk?

• A.
$$w_0^* = 2$$
, $w_1^* = 5$

• B.
$$w_0^* = 3$$
, $w_1^* = 10$

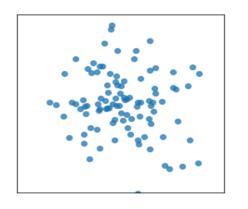

• C.
$$w_0^* = -2$$
, $w_1^* = 5$

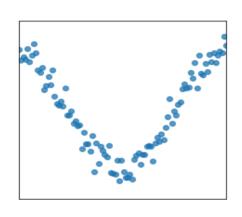

• D.
$$w_0^* = -5$$
, $w_1^* = 5$

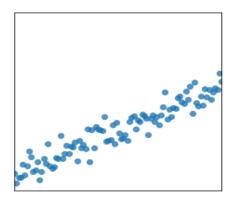

Correlation

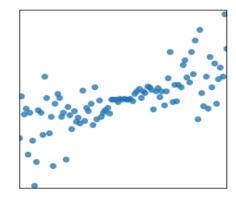

Quantifying patterns in scatter plots

- In DSC 10, you were introduced to the idea of the **correlation coefficient**, r.
- It is a measure of the strength of the linear association of two variables, x and y.
- Intuitively, it measures how tightly clustered a scatter plot is around a straight line.
- It ranges between -1 and 1.

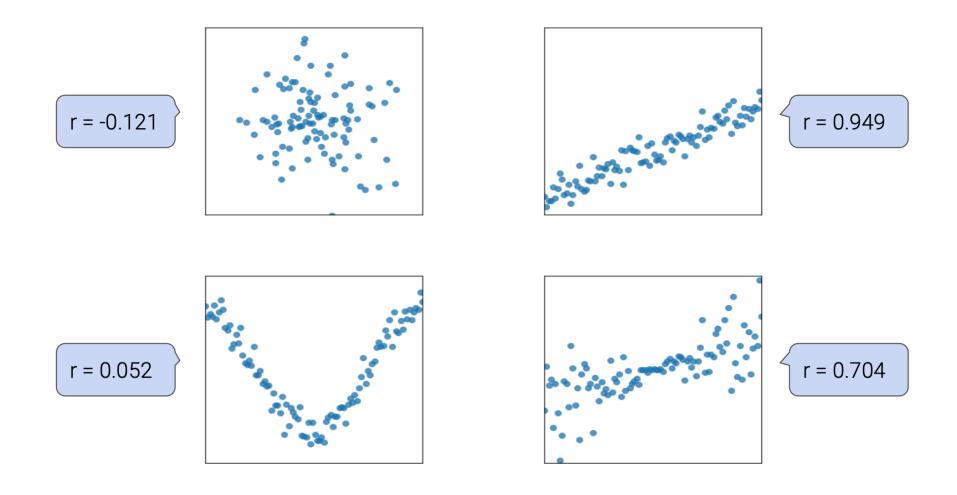

The correlation coefficient

- The correlation coefficient, r, is defined as the average of the product of x and y, when both are in standard units.
- Let σ_x be the standard deviation of the x_i s, and \bar{x} be the mean of the x_i s.
- x_i in standard units is $\frac{x_i \bar{x}}{\sigma_x}$.
- The correlation coefficient, then, is:

$$r = rac{1}{n} \sum_{i=1}^n \left(rac{x_i - ar{x}}{\sigma_x}
ight) \left(rac{y_i - ar{y}}{\sigma_y}
ight)$$

The correlation coefficient, visualized

Another way to express w_1^st

• It turns out that w_1^* , the optimal slope for the linear hypothesis function when using squared loss (i.e. the regression line), can be written in terms of r!

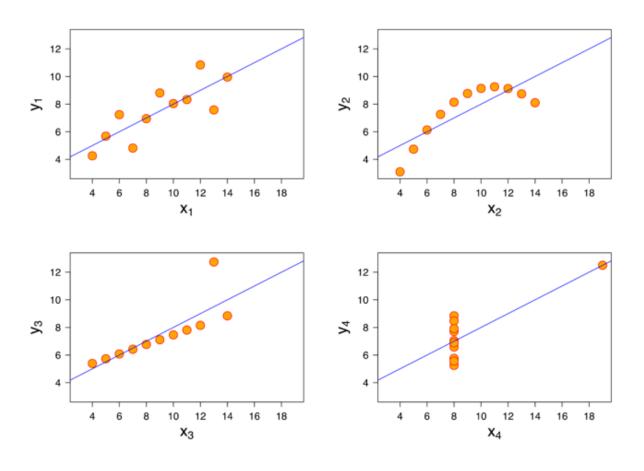

$$w_1^* = rac{\displaystyle\sum_{i=1}^n (x_i - ar{x})(y_i - ar{y})}{\displaystyle\sum_{i=1}^n (x_i - ar{x})^2} = r rac{\sigma_y}{\sigma_x}$$

- It's not surprising that r is related to w_1^* , since r is a measure of linear association.
- Concise way of writing w_0^* and w_1^* :

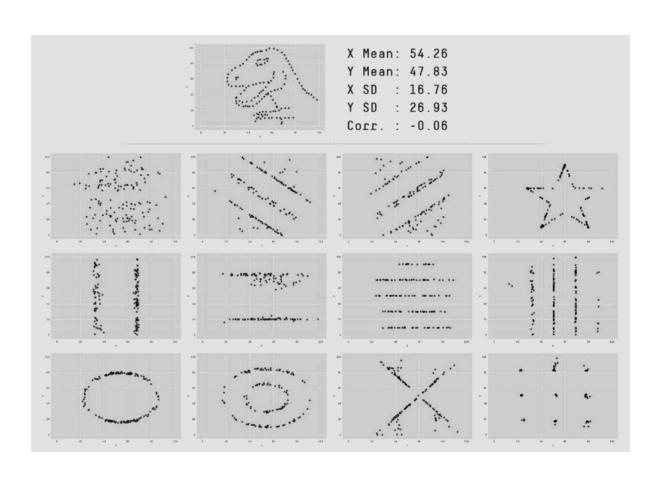

$$w_1^* = r rac{\sigma_y}{\sigma_x} \qquad w_0^* = ar{y} - w_1^* ar{x}$$

Proof that
$$w_1^* = r rac{\sigma_y}{\sigma_x}$$

Dangers of correlation

Dangers of correlation

Interpreting the formulas

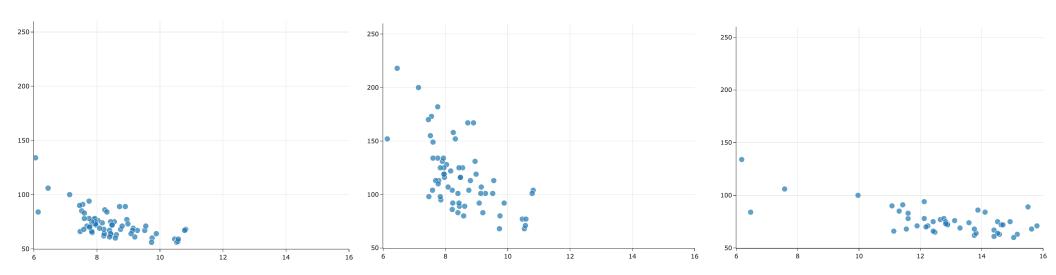

Interpreting the slope

$$w_1^* = r rac{\sigma_y}{\sigma_x}$$

- The units of the slope are units of y per units of x.
- In our commute times example, in H(x)=142.25-8.19x, our predicted commute time decreases by 8.19 minutes per hour.

Interpreting the slope

$$w_1^* = r rac{\sigma_y}{\sigma_x}$$

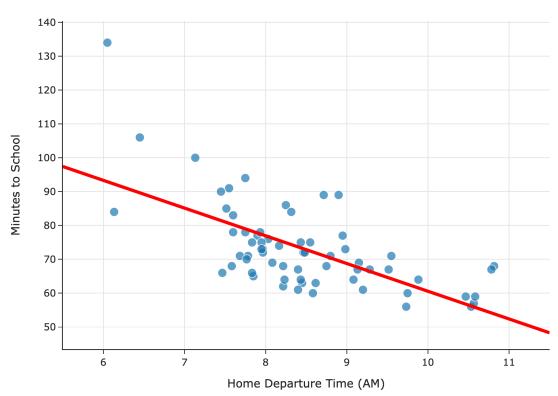

- Since $\sigma_x \geq 0$ and $\sigma_y \geq 0$, the slope's sign is r's sign.
- ullet As the y values get more spread out, σ_y increases, so the slope gets steeper.
- ullet As the x values get more spread out, σ_x increases, so the slope gets shallower.

Interpreting the intercept

$$w_0^*=ar{y}-w_1^*ar{x}$$

Predicted Commute Time = 142.25 - 8.19 * Departure Hour

What are the units of the intercept?

• What is the value of $H^*(\bar{x})$?

Question 🤔

Answer at q.dsc40a.com

We fit a regression line to predict commute times given departure hour. Then, we add 75 minutes to all commute times in our dataset. What happens to the resulting regression line?

- A. Slope increases, intercept increases.
- B. Slope decreases, intercept increases.
- C. Slope stays the same, intercept increases.
- D. Slope stays the same, intercept stays the same.

Correlation and mean squared error

• Claim: Suppose that w_0^* and w_1^* are the optimal intercept and slope for the regression line. Then,

$$R_{ ext{sq}}(w_0^*,w_1^*) = \sigma_y^2(1-\pmb{r}^2)$$

- That is, the mean squared error of the regression line's predictions and the correlation coefficient, *r*, always satisfy the relationship above.
- Even if it's true, why do we care?
 - \circ In machine learning, we often use both the mean squared error and r^2 to compare the performances of different models.
 - If we can prove the above statement, we can show that finding models that minimize mean squared error is equivalent to finding models that maximize r^2 .

Proof that
$$R_{ ext{sq}}(w_0^*,w_1^*)=\sigma_y^2(1-r^2)$$

Connections to related models

Question 🤔

Answer at q.dsc40a.com

Suppose we chose the model $H(x)=w_1x$ and squared loss. What is the optimal model parameter, w_1^* ?

$$ullet$$
 A. $rac{\sum_{i=1}^n (x_i-ar{x})(y_i-ar{y})}{\sum_{i=1}^n (x_i-ar{x})^2}$

$$ullet$$
 B. $rac{\sum_{i=1}^n x_i y_i}{\sum_{i=1}^n x_i^2}$

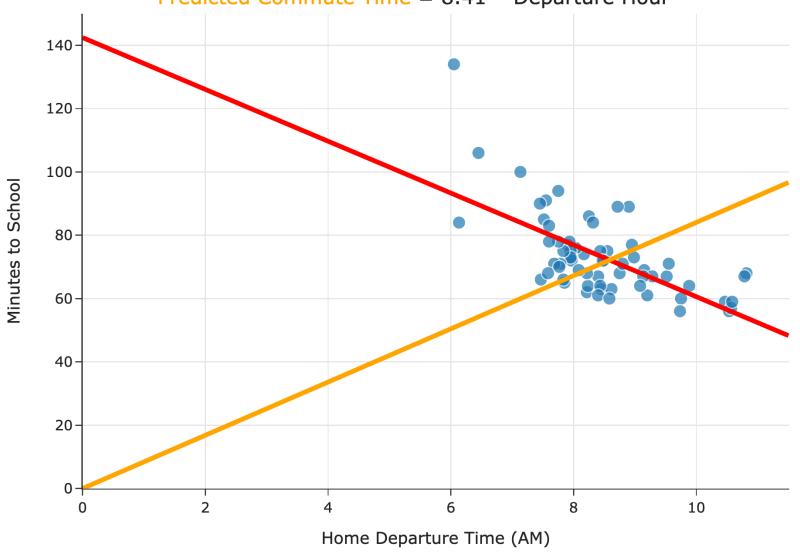

$$ullet$$
 C. $rac{\sum_{i=1}^n x_i y_i}{\sum_{i=1}^n x_i^2}$

$$ullet$$
 D. $rac{\sum_{i=1}^n y_i}{\sum_{i=1}^n x_i}$

Exercise

Suppose we chose the model $H(x)=w_1x$ and squared loss. What is the optimal model parameter, w_1^st ?

Predicted Commute Time = 142.25 - 8.19 * Departure Hour Predicted Commute Time = 8.41 * Departure Hour

Exercise

Suppose we choose the model $H(x)=w_0$ and squared loss. What is the optimal model parameter, w_0^st ?

Comparing mean squared errors

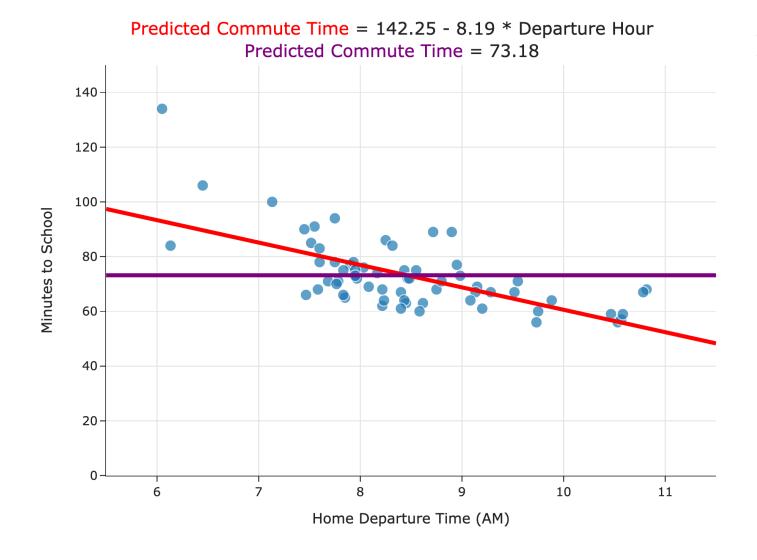

- With both:
 - \circ the constant model, H(x)=h, and
 - \circ the simple linear regression model, $H(x)=w_0+w_1x$,

when we chose squared loss, we minimized mean squared error to find optimal parameters:

$$R_{ ext{sq}}(H) = rac{1}{n} \sum_{i=1}^n \left(y_i - H(x_i)
ight)^2$$

Which model minimizes mean squared error more?

Comparing mean squared errors

$$ext{MSE} = rac{1}{n} \sum_{i=1}^n \left(y_i - H(x_i)
ight)^2$$

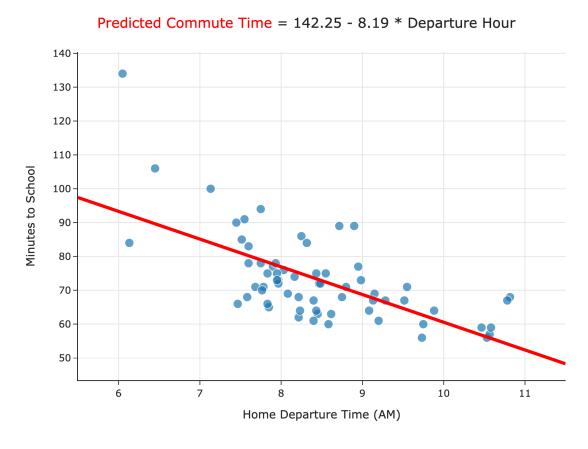

- The MSE of the best simple linear regression model is ≈ 97 .
- ullet The MSE of the best constant model is pprox 167

•

 The simple linear regression model is a more flexible version of the constant model.

Causality

Solving for best linear model for commute

Can we conclude that leaving later causes you to get to school quicker?

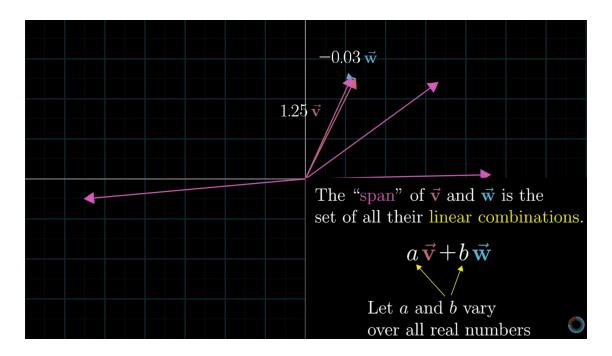

Linear algebra review

Wait... why do we need linear algebra?

- Soon, we'll want to make predictions using more than one feature.
 - Example: Predicting commute times using departure hour and temperature.
- Thinking about linear regression in terms of **matrices and vectors** will allow us to find hypothesis functions that:
 - Use multiple features (input variables).
 - \circ Are non-linear, e.g. $H(x)=w_0+w_1x+w_2x^2$.
- Before we dive in, let's review.

Spans of vectors

- One of the most important ideas you'll need to remember from linear algebra is the concept of the **span** of two or more vectors.
- To jump start our review of linear algebra, let's start by watching this video by 3blue1brown.

Next time

- We'll review the necessary linear algebra prerequisites.
- We'll then start to formulate the problem of minimizing mean squared error for the simple linear regression model using matrices and vectors.
- We'll send some relevant linear algebra review videos on Ed.
